WATER YEAR 2017 SUMMARY

This report summarizes the 2017 Water Year (WY2017) discharge results for the 14 stations that were installed in the Big Barren Creek watershed in 2015 and 2016. The 2017 Water Year runs from October 1, 2016 to September 30, 2017. Big Barren Creek is a tributary of the Current River Basin (8-digit Hydrological Unit Code (HUC) #11010008) located in portions of Ripley, Oregon and Carter Counties in southeast Missouri (Figure 1). Gaging station locations were selected along both the main stem of Big Barren Creek and distributed along smaller tributaries throughout the watershed (Figure 2). Drainage areas for the tributary sites ranged from 1.59-7.82 km² and gage locations within the smaller tributary watersheds drain forest service lands that have either been entirely burned or unburned (Table 1). The drainage areas of the main stem sites have a mix of land uses from private lands, to burned and unburned public forest, ranging in drainage area from 8.82-183.1 km². The majority of the streams within the Big Barren Creek watershed are ephemeral due to the underlying karst landscape where sinkholes, losing streams, and caves are common (Weary et al., 2014). Perennial sections of these streams are located within, or just downstream, of the Big Barren Creek Natural Area and the Cowards Hollow Natural Area which appear to be associated with a series of northeast trending faults (Weary et al., 2014; Figure 2).

Stage data was recorded every 5-minutes using Hobo U20L-04 Water Level Loggers. The level loggers were installed inside a PVC pipe assembly and secured to 1-2 m staff gages that were installed at each site. An additional level logger was installed to measure barometric pressure used to compensate for barometric pressure changes. Raw data is downloaded periodically (~ every 10 weeks) from the level loggers using the Hobo Waterproof Shuttle. Discharge rating curves were created at each site to estimate flows for each 5-minute stage reading over the monitoring period. Specific methods used to develop these rating curves can be seen in a separate report (Owen et al., 2020). For 13 of the 14 sites there were less than 2 days of missing data over the year. However, at Cowards Hollow there was over 36 days of missing data due to equipment problems.

Rainfall

There was a total of 127.1 cm of rainfall in WY2017, which is 7.8 cm higher than the average annual rainfall for the area between 1956-2014 (Pavlowsky et al., 2016). Of that total, 62.0 cm (49%) of the total annual rainfall came in the spring from April to June (Figure 3). Very high rainfall amounts occurred between April 28-30 that saw as much as 25 cm of rainfall in some areas of southern Missouri that produced extreme floods causing infrastructure damage and set peak discharge records at several USGS gaging stations in the Ozarks (Heimann et al., 2018). In the Big Barren Creek watershed, these storms produced over 14 cm of rainfall from April 28-

30, with nearly 12 cm falling on April 30th alone. This event caused extreme flooding, widespread stream erosion, and damaged many of the road crossings within the watershed (Owen et al, 2018). The second highest seasonal rainfall total occurred in the winter from January-March with 26.6 cm (20.9%) of the total annual rainfall. The lowest seasonal rainfall occurred in the fall from October-December with 16.8 cm (13.2%).

Discharge and Runoff

The range in discharge values for WY2017 were calculated for both perennial and ephemeral gaging stations in the Big Barren Creek watershed and annual average discharges are comparable to nearby USGS gaging stations. Average discharge for the perennial sites ranged from 0.047 m³/s at CH to 1.77 m³/s at LNA (Table 2). For ephemeral sites, average annual discharge ranged from 0.008 m³/s at TH to 1.76 m³/s at LBB. Station BH only recorded partial flows as it was recently discovered a portion of the flow in the channel jumps to the road ditch upstream of the gaging station. Therefore, data produced at this site is far lower than the other gaging stations. Annual peak discharge ranged from 16.9 m³/s at TH to 409.8 m³/s at LBB. Minimum discharge at the perennial sites ranged from 0.006 m³/s at CH to 0.115 m³/s at UNA. Average annual discharge for the sites from this study were plotted by drainage area and compared to nearby USGS gaging stations (Table 3). Ephemeral sites plot below the best-fit line of perennial USGS stations and perennial sites plot on or just below the USGS stations (Figure 4). Furthermore, the USGS station along a losing section of Logan Creek near Ellington plots along the best-fit line of the ephemeral sites in this study.
